ABSTRACT
Now days the researchers are focusing on the fast dissolving dosage form (FDDF’s). The fast dissolving dosage forms include the mouth dissolving tablets, mouth dissolving thin films. The alternative words used for these dosage forms are fast disintegrating, orodispersible, fast dissolving. The oral thin film technology (OTF’s) is a dissolvable film technology have evolved from a purely confectionery novelty from a drug delivery platform. The OTH dosage form dissolves in the mouth without need of water and within 10-15 seconds is the novelty of this dosage form. On the basis of this novelty many patents are available in the US country. Intraoral delivery is particularly beneficial to patients with special needs that are unable to tolerate traditional oral (entrathrough GI track) administration due to nausea, vomiting or dysphasia. Many pharmaceutical companies focusing on this Oral thin film technology. Today, this film technology is approved by is approved by FDA.

Keywords: Oral Thin Film, Pullulan, Folding Endurance

INTRODUCTION
Fast-dissolving drug-delivery systems were first developed in the late 1970s as an alternative to conventional dosage forms for pediatric and geriatric patients who experience difficulties in swallowing traditional oral solid-dosage forms1. These films are made up of the water soluble polymer which when placed on the tongue instantly dissolves or disintegrate the medication without need of water. These films are suitable for the pediatric patients and avoids nausea, vomiting or dysphasia caused due to oral administration of traditional dosage forms2. The evolution of thin film dosage forms are described in figure:1 form confectionary use to current pharmaceutical application3.

TYPES OF MOUTH DISSOLVING FILM
A. Flash release film. 
B. Flash Dispersible film. 
C. Non-disintegrating mucosahhesive films. 
D. Medium disintegrating mucoadhesive films.

Advantages
a) No special training is required for the administration of dosage form.
b) No need of water, drug wet by saliva and instantly dissolves or disintegrates.
c) Availability of larger surface area for drug absorption.
d) Destructive acidic environment effect of stomach can be avoided.
e) Site specific and rapid onset of action.
f) Drug enter systemic circulation with reduced hepatic first pass effect.

Disadvantage
a) Higher doses cannot be incorporated. 
b) These dosage forms are moisture sensitive.

GENERAL PROPERTIES AND RELEASE MECHANISM
The Quick-Dis™ drug delivery system comprises a thin, printable, low-moisture, non-tacky film that is convenient for dosing, suitable for labeling, and flexible for easy packing, handling and application. These films are 1-10mm in thickness and having total surface area about 1-20 cm². These thin films when comes in contact with the saliva rapidly hydrates and breaks after softening release the medicaments. The typical disintegration time when comes in contact with the water is about 1-30 seconds5.

COMPOSITION OF MOUTH DISSOLVING FILM
A typical composition of mouth dissolving film contain following polymer.

Active pharmaceutical ingredients
The API used in formulation of the film is in the percentage of the 1-25% with small dose. The micronized API is best suitable candidate for the formulation of the thin film which improves dissolution rate and uniformity in the film. For poorly water insoluble drugs the film is prepared by increasing solubility by complexation with various cyclodextrin. The poloxamer 407 is surfactant used to increase solubility with this complex.20 Following are some drug candidate which are used in mouth dissolving film formulation22-26.

Film forming agents:
Film forming agents are water polymers which are used in formulation of thin film. These are HPMC E5, HPMC E15, HPMC E50, Microcrystalline Cellulose, gelatin Polyvinyl alcohol, Gelatin, Eudragit, Maltodextrin, Pullulans 27.

Plasticizers
The plasticizers are used in the formulation of mouth dissolving film to increase the flexibility by reducing the glass transition temperature of the film. Improper use of plasticizers may affect the mechanical properties of the film. The commonly used plasticizers are PEG 400, Glycerol, Propylene Glycol, Acetyl citrate castor oil etc.28.

Sweetening agents
The sweetening agent used in formulation of mouth dissolving film is used for the purpose of taste masking of some bitter drug and good mouth feel. The commonly used sweetening agents are Fructose, Sucrose, Maltose, Neotame, Aspartame, Mannitol, Sorbitol, Glucose.29 Neotame and Aspartame is sweeter than sucrose. Acetosulfame-K and sucralose have more than 2000 and 8000 times sweetening power as compared to sucrose. Rebiana which is an herbal sweetener, derived from plant stevia rebaudiana(south African plant) has more than 200-300 time sweetness but these synthetic sweeteners carry a disadvantage of after taste effect which can be reduced by mixing or blending the natural and synthetic sweeteners. The amalgamation of sweeteners may lead to synergism and improvement in of the formulation.30

Saliva stimulating agents31-32
The purpose of using saliva stimulating agents is to increase the rate of production of saliva that would aid in the faster disintegration of the rapid dissolving strip formulations. Generally acids which are used in the preparation of food can be utilized as salivary stimulants. Citric acid, malic acid, lactic acid, ascorbic acid and tartaric acid are the few examples of salivary stimulants, citric acid being the most preferred amongst them. These agents are used alone or in combination between 2 to 6%w/w of weight of the strip.

Surfactant
Surfactants are used as solubilising or wetting or dispersing agent so that the film is getting dissolved within seconds and release active agent immediately. Some of the commonly used are sodium lauryl sulfate, benzalkonium chloride, bezthonium chloride, tweens etc. One of the most important surfactant is poloxamer 407 that is used as solubilizing, wetting and dispersing agent.33

Colouring agents
Pigments such as Titanium dioxide or FD & C approved colouring agent are incorporated (not exceeding concentration of 1% w/w) in solution.

ORAL FILM MANUFACTURING METHODS
The oral film manufacturing process includes
1. Solvent Casting Method
2. Hot Melt Extrusion
3. Solid Dispersion Extrusion
4. Rolling Method

1. Solvent Casting Method
The steps in involved solvent casting method are
- Water-soluble hydrocolloids (polymer) are dissolved to form a homogenous viscous solution
- API and other ingredients are dissolved in smaller amounts of aqueous using a high-shear processor
- The entrapped air is removed from the viscous solution by vacuum
- Coated on a non-treated casting film
- Sent to aeration-drying oven and subsequently wound onto roll stock.
- As described in Figure 2

2. Hot Melt Extrusion
- The API and other ingredients are mixed in a dry state
- Filled in the hopper
- Conveyed, mixed, and melted by the extruder
- After being subjected to the heating process and extruded out in a molten state, a die then shapes the melt in the required film form.
- As described in Figure 3.

3. Rolling method
In rolling method solution or suspension containing drug is rolled on carrier. The solvent is mainly water and mixture of water and alcohol. The film is dried on rollers and cut into desired shape and sizes.34

EVALUATION TEST FOR MOUTH DISSOLVING FILM
1. Uniformity of dosage units of the preparation
The uniformity of dosage units of the oral film preparation was tested using 20 preparations, and the content of drug was determined by analytical method. The acceptance value (AV) of the preparation is less than 15%, according to the JP15 (Japanese pharmacopoeia). AV for JP15 was calculated according to the following Eq.

\[ AV = \frac{\text{M} - \text{X}}{\text{X}} \times 100 \%
\]

where M is label claim (100%), X is the average (%) of individual contents, k is the acceptability constant (2.2), s is the standard deviation. In USP27, the contents of major component in the preparation should be within a range between 85% and 115% and the relative standard deviation should be less than or equal to 6.0%.

2. Thickness
The thickness of strip can be measured by micrometer screw gauge at different strategic locations. This is essential to ascertain uniformity in the thickness of the film as this is directly related to the accuracy of dose in the strip.

3. Tack tests
Tack is the tenacity with which the strip adheres to an accessory (a piece of paper) that has been pressed into contact with the strip. The alternative name for this test is dryness test. With help of this test film is checked for dry to handle, dry to touch, dry to print, dry to recoat.
4. Tensile strength
Tensile strength is the maximum stress applied to a point at which the strip specimen breaks. It is calculated by the applied load at rupture divided by the cross-sectional area of the strip as given in the equation below:

\[
\text{Tensile Strength} = \frac{\text{Load at Failure}}{\text{Thickness \times width}}
\]

5. Percent Elongation
When stress is applied, a strip sample stretches and this is referred to as strain. Strain is basically the deformation of strip divided by original dimension of the sample. Generally elongation of strip increases as the plasticizer content increases.

\[
\%\text{Elongation} = \frac{\text{Increase in length of strip}}{\text{Initial length of strip}} \times 100
\]

6. Tear resistance
Tear resistance of plastic film or sheeting is a complex function of its ultimate resistance to rupture. Basically very low rate of loading 51mm (2 in.)/min is employed and is designed to measure the force to initiate tearing. The maximum stress or force (that is generally found near the onset of tearing) required to tear the specimen is recorded as the tear resistance value in Newton’s (or pounds-force).

7. Young's modulus
Young's modulus or elastic modulus is the measure of stiffness of strip. It is represented as the ratio of applied stress over strain in the region of elastic deformation as follows:

\[
\text{Young modulus} = \frac{\text{Slope}}{\text{strip thickness \times cross-head speed}}
\]

Hard and brittle strips demonstrate a high tensile strength and Young's modulus with small elongation.

8. Folding Endurance
Folding endurance is determined by repeated folding of the strip at the same place till the strip breaks. The number of times the film is folded without breaking is computed as the folding endurance value.

9. Disintegration Time
The disintegration time limit of 30 s or less for orally disintegrating tablets described in CDER guidance can be applied to fast dissolving oral strips. Although, no official guidance is available for oral fast disintegrating films/strips, this may be used as a qualitative guideline for quality control test or at development stage. Pharmacopeial disintegrating test apparatus may be used for this study. Typical disintegration time for strips is 5–30 s.

10. Dissolution Test
Dissolution testing can be performed using the standard basket or paddle apparatus described in any of the pharmacopoeia. The dissolution medium will essentially be selected as per the sink conditions and highest dose of the API. Many times the dissolution test can be difficult due to tendency of the strip to float onto the dissolution medium when the paddle apparatus is employed.

11. Assay/drug content and content uniformity
This is determined by any standard assay method described for the particular API in any of the standard pharmacopoeia. Content uniformity is determined by estimating the API content in individual strip. Limit of content uniformity is 85–115%.
