ABSTRACT
A simple, sensitive, accurate, precise and economical visible spectrophotometric method was developed and validated for the estimation of amoxicillin trihydrate in tablets. The method is based on the reaction of amoxicillin trihydrate with ninhydrin reagent in methanol giving blue color chromogen, which shows maximum absorbance at 578 nm against reagent blank. The chromogen obeyed Beer’s law in the concentration range of 10-80 µg/ml for amoxicillin trihydrate. The results of the analysis have been validated statistically and by recovery studies.

Key words: Amoxicillin trihydrate, Chromogen, Ninhydrin reagent, Visible spectrophotometric, Tablet.

INTRODUCTION
Amoxicillin trihydrate (CFD) is chemically, 6-(P-hydroxy-alpha-aminophenylacetamido) penicillanic acid trihydrate1. Amoxicillin trihydrate is the 4-hydroxy analogue of ampicillin and is used similarly in susceptible infections caused by gram-positive and gram-negative bacteria2. Amoxicillin trihydrate is official in IP, USP and BP3, USP4 and BP5 describes liquid chromatography method for the estimation of amoxicillin trihydrate. Literature survey reveals voltametric6, capillary chromatography7, flow injection analysis8, spectrophotometric9,10 and HPLC11-16 methods for the estimation of amoxicillin trihydrate in biological fluids and in pharmaceutical formulations. The present communication describes simple, sensitive, accurate, precise and economical visible spectrophotometric method using ninhydrin reagent for the estimation of amoxicillin trihydrate in tablet dosage form.

MATERIALS AND METHODS
Apparatus
A Shimadzu model 1601 double beam UV/Vis. spectrophotometer with spectral width of 2 nm, wavelength accuracy of 0.5 nm and a pair of 10 nm matched quartz cells was used to measure absorbance of the resulting solutions. A Sartorius CP224S analytical balance (Germany), an ultra sonic cleaner (Frontline FS 4, Mumbai, India), water bath (Cintex Industrial Corporation, Mumbai, India) were used in the study.

Reagents and Materials
Amoxicillin trihydrate powder was procured as a gift sample from Mann Pharmaceuticals Ltd, Mehsana, Gujarat, India. The commercially available tablets of amoxicillin trihydrate were procured from local market. Ninhydrin reagent and methanol (AR Grade, S.D. Fine Chemicals Ltd., Mumbai) were used in the study.

Preparation of reagent and standard stock solution
Accurately weighed ninhydrin powder (500 mg) was transferred to a 100 ml volumetric flask, dissolved in and diluted to the mark with methanol (0.5% w/v). Accurately weighed amoxicillin trihydrate (20 mg) was transferred to a 100 ml volumetric flask, dissolved in and diluted to the mark with methanol. (200 µg/ml).

Methodology
Standard stock solution of amoxicillin trihydrate (2.0 ml) was transferred to a 10 ml conning volumetric flask. Ninhydrin reagent (1.5 ml) was added and mixed. The flask was immersed in a water bath at 92 ± 1°C for 20 minutes, cooled to room temperature and the volume was adjusted to 10 ml with methanol. The absorbance of the colored solution was scanned in the range of 400 to 800 nm against reagent blank, prepared similarly in which volume of standard solution was replaced by an equal volume of methanol. Maximum absorbance was obtained at 578 nm.

Optimization of different conditions
Effect of concentration of ninhydrin reagent
Standard stock solution of amoxicillin trihydrate (2.0 ml) was transferred to a series of 10 ml corning volumetric flasks. To each flask, different volumes of ninhydrin reagent (0.5, 1.0, 1.5, 2.0, 2.5, 3.0, 3.5 and 4.0 ml) was added and mixed. The flasks were immersed in a water bath at 92 ± 1°C for 20 minutes, cooled to room temperature and the volume in each flask was adjusted to 10 ml with methanol. The absorbance of the resulting solutions was measured at 578 nm against reagent blank. Maximum absorbance was observed in the presence of 1.5 ml of 0.5% w/v ninhydrin reagent.

Effect of temperature
Standard stock solution of Amoxicillin trihydrate (2.0 ml) was transferred to a series of 10 ml corning volumetric flasks. To each flask, 1.5 ml of ninhydrin reagent was added and mixed and heated at different temperatures (40°C, 50°C, 60°C, 70°C, 80°C, 90°C, 92°C, 94°C and 96°C) for 20 minutes, cooled to room temperature and the volume in each flask was adjusted to 10 ml with methanol. The absorbance of the resulting solutions was measured at 578 nm against reagent blank. Optimum temperature to obtain maximum absorbance was found to be 92 ± 1°C.

Time for maximum color development and color stability
Standard stock solution of amoxicillin trihydrate (2.0 ml) was transferred to a series of 10 ml corning volumetric flasks. To each flask, 1.5 ml of ninhydrin reagent was added and mixed. The flasks were immersed in a water bath at 92 ± 1°C for different time intervals (5, 10, 15, 20, 25, 30, 45 and 60 minutes), cooled to room temperature and the volume in each flask were adjusted to 10 ml with methanol. The absorbance of the resulting solutions was measured at 578 nm against reagent blank. Maximum absorbance was obtained after 20 minutes, which remained constant for 1 h.

Validation of the proposed method
The proposed method was validated according to the International Conference on Harmonization (ICH) guidelines17.

Linearity
Calibration curve was plotted over a concentration range of 10-80 µg/ml for amoxicillin trihydrate. Accurately measured standard stock solutions of amoxicillin trihydrate (0.5, 1.0, 1.5, 2.0, 3.0 and 4.0 ml) were transferred to a series of 10 ml corning volumetric flasks. To each flask, 1.5 ml of ninhydrin reagent was added and mixed. The flasks were immersed in a water bath at 92 ± 1°C for 20
minutes, cooled to room temperature and the volume in each flask was adjusted to 10 ml with methanol. The absorbance of the resulting solutions was measured at 578 nm against reagent blank. Calibration curve was constructed for amoxicillin trihydrate by plotting concentration versus absorbance at 578 nm. Each reading was an average of five determinations.

**Accuracy (% Recovery)**

The accuracy of the method was performed by calculating recovery of amoxicillin trihydrate by the standard addition method. Known amounts of standard solutions of amoxicillin trihydrate were added at 50, 100 and 150% levels to prequantified sample solutions of amoxicillin trihydrate (30 µg/ml). Each sample was prepared in triplicate at each level. The amount of amoxicillin trihydrate was estimated by applying obtained values to regression equation.

**Method Precision (% Repeatability)**

The precision of the instrument was checked by repeated scanning and measurement of the absorbance of solutions (n = 6) of amoxicillin trihydrate (20 µg/ml) without changing the parameters for the method. The repeatability was expressed in terms of relative standard deviation (%RSD).

**Intermediate Precision (Reproducibility)**

The intraday and interday precision of the proposed method was performed by analyzing the corresponding responses 3 times on the same day and on 3 different days over a period of 1 week for different concentrations of standard solutions of amoxicillin trihydrate (10-80 µg/ml). The results were reported in terms of relative standard deviation (%RSD).

**Limit of Detection (LOD) and Limit of Quantification (LOQ)**

The limit of detection (LOD) and the limit of quantification (LOQ) of the drug was derived by calculating the signal-to-noise ratio (S/N, i.e., 3.3 for LOD and 10 for LOQ) using the following equations as per International Conference on Harmonization (ICH) guidelines.1,7

\[ \text{LOD} = 3.3 \times \frac{\sigma}{S} \]

\[ \text{LOQ} = 10 \times \frac{\sigma}{S} \]

Where \( \sigma \) = the standard deviation of the response and \( S \) = Slope of calibration curve.

**Estimation of amoxicillin trihydrate from pharmaceutical tablet dosage form**

Twenty tablets were accurately weighed and powdered. A quantity of powder equivalent to 20 mg of amoxicillin trihydrate was transferred to a 100 ml volumetric flask and mixed with methanol (50 ml) and sonicated for 20 minutes. The solution was filtered through Whatman filter paper No. 41 and the residue was washed thoroughly with methanol. The filtrate and washings were combined in a 100 ml volumetric flask and diluted to the mark with methanol. The solution (3.0 ml) was transferred to a 10 ml conical volumetric flask. Ninhydrin reagent (1.5 ml) was added and mixed. The flask was immersed in a water bath at 92 ± 1°C for 20 minutes, cooled to room temperature and the volume was adjusted to 10 ml with methanol. The absorbance of the resulting solution was measured at 578 nm against reagent blank. The amount of amoxicillin trihydrate present in tablet solution was determined by fitting the responses into the regression equation. The analysis procedure was repeated five times with tablet formulation.

**RESULTS AND DISCUSSION**

Ninhydrin reagent is mainly used for the detection of free amino and carbonyl groups in proteins and peptides, yielding a blue color under the proper condition.19,20 Ninhydrin (triketohydrindien hydrate) reacts with amino group containing substances like amino acids, proteins and peptides and when heated under proper conditions, produce ammonia, carbon dioxide and blue purple complex.19-22 Literature survey reveals spectrophotometric method for the determination of lisinopril using ninhydrin reagent.23 Therefore it was thought of interest to extend the application of ninhydrin reagent in the estimation of amino group containing drugs like amoxicillin trihydrate.

In the proposed method, reagent solution and standard stock solutions of drugs were prepared in methanol. Various reaction conditions were established by varying one parameter at a time and keeping the others fixed by observing the effect produced on the absorbance of the colored species. The parameters involved for maximum color development viz. concentration of ninhydrin reagent, temperature and heating time required to yield chromogen of maximum color intensity and stability were optimized. In this method all these parameters were strictly followed. The blue colored complex formed having wavelength of maximum absorbance at 578 nm (Figure 1). In proposed method, it was found that 1.5 ml of 0.5% w/v ninhydrin reagent (Figure 2), 92 ± 1°C heating temperature (Figure 3) and 20 minutes heating time (Figure 4) was sufficient for the development of maximum color intensity. Stability study of the developed chromogen was carried out by measuring the absorbance values at a time intervals of 20 minutes for 3 h and it was found to be stable for more than 2 h for the drugs at room temperature.

The linearity was found in the concentration range of 10 to 80 µg/ml (r² = 0.9995). The reproducibility, repeatability and precision of method are very good as shown by the low values of standard deviation and relative standard deviation (%RSD). The % recovery value in the range of 98.15 to 100.3 % for tablet indicates non-interferences from the formulation excipients. The data of recovery studies and assay results are given in Table 1 and Table 2, respectively. Optical characteristics of method and summary of validation parameters for amoxicillin trihydrate was given in Table 3.

**CONCLUSION**

The proposed visible spectrophotometric method was found to be, simple, sensitive, accurate, precise and economic for determination of amoxicillin trihydrate in tablet dosage form. Hence it can be conveniently adopted for routine quality analysis of the drug in pharmaceutical dosage form.

**ACKNOWLEDGEMENT**

The authors are thankful to Mann Pharmaceutical Limited, Mehsana, Gujarat, India for providing gift sample of amoxicillin trihydrate for research. The authors are highly thankful to Shree S. K. Patel College of Pharmaceutical Education & Research, Ganpat University, Kherva, Mehsana, Gujarat, India for providing all the facilities to carry out the work.
